impulse–momentum theorem quantifies collision forces, and the work–energy theorem connects drag to propulsive power (Campbell, 2025). The rotational analogue, $\sum \tau = I\alpha$, and the conservation of angular momentum explain why single-screw vessels heel under propeller torque reaction and why gyroscopic effects couple pitch and yaw in high-speed craft. At the most general level, the SNAME six-DOF formulation captures the coupled translational and rotational dynamics of a marine vehicle in a single compact equation, $\mathbf{M}_{RB}\dot{\boldsymbol{\nu}} + \mathbf{C}_{RB}\boldsymbol{\nu} = \boldsymbol{\tau}_{RB}$, from which all simpler models can be recovered as special cases (Al Makdah et al., 2019).

The collision mechanics developed in this chapter—from Newtonian impulse through the coefficient of restitution to closed-form collision energy loss expressions (Zhang, 1999)—quantify the enormous energies involved when ships collide. Energy methods, codified in the conservation law $\Delta E_{\text{mech}} = W_{\text{nc}}$, provide the bridge between the force-based and energy-based descriptions of ship performance, and the simple harmonic motion framework connects the same principles to the oscillatory behaviour of roll, pitch, and heave that dominates seakeeping (Russell et al., 2015).

Manoeuvring analysis extends these principles to curved motion. The classical rudder-force expression and the resulting heel angle during a turn demonstrate that course changes at speed carry direct stability implications (Attwood, 1899). The free-body-diagram approach and the pleometric index proposed by Fuss (2023) provide a modern, dimensionless framework for quantifying turn severity. Throughout, the same small set of mechanical principles—force balance, momentum conservation, energy conservation, rotational dynamics, and simple harmonic motion—reappears in contexts ranging from sail propulsion to collision energy absorption to ship rolling (Russell et al., 2015).

Two limitations apply. First, all drag and resistance expressions in this chapter assume calm water and steady flow; the modifications required for waves, currents, and unsteady motion are developed in Chapters 5 and 6. Second, the added-mass terms that appear in the manoeuvring equations (Equation 2.9) and the six-DOF formulation (Equation 2.15) are treated here as given coefficients; their physical origin in the acceleration of surrounding fluid is addressed in Chapter 5. With these caveats, the Newtonian mechanics of this chapter provides the foundation for the hydrodynamic, structural, and propulsive analyses that follow.

partment flooding—extends the lost buoyancy method introduced here into the probabilistic framework presented in the *Maritime Safety and Risk Physics* chapter of the companion volume. Finally, the Bonjean-curve technique introduced for static conditions provides the starting point for evaluating hull girder loads in waves (see the *Structural Mechanics of Ships* chapter of the companion volume), where the instantaneous waterline varies along the ship's length.

uncertainty (Attwood, 1899; United States Naval Academy, 2021). For the NACRA 17 foiling catamaran, the equilibrium condition $RM \geq HM$ takes a distinctive form: crew righting moment ($RM_{\text{crew}} = m_{\text{crew}} \cdot g \cdot d_{\text{crew}}$) is the primary stability contribution, and the depth-dependent lift of surface-piercing Z-foils provides passive pitch stabilisation (Huchet, 2021). The box-shaped approximation $GM_0 \approx B^2/(12T) - KG + T/2$ enables rapid preliminary assessment from principal dimensions alone, and the correct response to a vessel at her angle of loll—lowering the centre of gravity, never adding weight on the high side—follows directly from the physics of the wall-sided formula (Ridley & Patterson, 2014).

Modern stability regulation has moved from deterministic damage scenarios to physics-based probabilistic frameworks. The attained subdivision index A (Equations 4.22–4.23) integrates survivability over all feasible damage cases weighted by their probability of occurrence (Guedes Soares & Santos, 2015), and random-forest classifiers trained on damage stability calculations can now predict residual GZ curve parameters from damage descriptors, accelerating the probabilistic framework while retaining physical accuracy (Sutulo & Guedes Soares, 2023). The IMO weather criterion ($A_1 \geq A_2$) formalises dynamical stability as an energy balance under combined steady wind and gust conditions (Lee, 2019). The Second Generation Intact Stability Criteria extend this philosophy to five physics-based failure modes—pure loss of stability, parametric roll, surf-riding/broaching, dead ship condition, and excessive acceleration—using a three-level assessment (algebraic, probabilistic vulnerability, direct time-domain simulation) that mirrors the proportionality principle already established for damage stability (Spyrou et al., 2023). Together, these frameworks transform ship stability from a static metacentric calculation into a comprehensive, risk-informed discipline that links hull geometry, loading condition, and the seaway environment within a unified analytical structure.

formulation $R_{\text{wind}} \propto C_r V_{\text{app}}^2 (A_T \cos^2\alpha + A_L \sin^2\alpha)$ (Rawson & Tupper, 2001) and the added resistance in waves complete the external force inventory for powering calculations in a seaway.

The Gothenburg 2000 CFD benchmark provides the quantitative standard against which computational resistance predictions are judged. The V&V framework decomposes simulation error into modelling and numerical contributions ($\delta_S = \delta_{SM} + \delta_{SN}$) and defines validation as $|E| < U_V = \sqrt{U_D^2 + U_{SN}^2}$ (Larsson et al., 2003). Across 20 RANS codes and three hull forms, the coefficient of variation in total resistance was approximately 5%, with numerical uncertainties of 2–6%. A particularly significant finding was that the form factor $(1 + k)$ increases by over 50% from model to full scale for a VLCC hull (0.247 $\rightarrow$ 0.378), contradicting the constant-form-factor assumption embedded in the standard ITTC extrapolation and suggesting that RANS-based full-scale simulations may ultimately provide more reliable powering predictions (Larsson et al., 2003). The extension of resistance physics to specialised environments—shallow water, where wave-making resistance doubles as $F_{nh} \rightarrow 1$, and polar waters, where ice-breaking constraints alter the optimal bow geometry—demonstrates that while the fundamental drag physics ($F \propto V^2$) is universal, optimal hull form is sensitive to the operating boundary conditions (Sutulo & Guedes Soares, 2023).

order as forward loads (Hernández-Fontes et al., 2020). These theoretical and computational tools—from Froude's nineteenth-century rolling experiments through strip theory and fully nonlinear potential flow to RANS-based viscous simulations—collectively provide the quantitative basis for operability assessment, hull form optimisation, and weather routing in contemporary naval architecture (Molland, 2008; Rawson & Tupper, 2001).

(Equation 8.40) from 0.84 to 1.0 (Grift et al., 2021). Wave energy converters exploit resonance tuning to maximise power extraction, achieving Relative Capture Widths of approximately 47–50% in Mediterranean sea states (Equation 8.42) (Pozzi et al., 2018). Whether the propulsor is a sail, a screw, an oar, or a pendulum oscillator, the governing framework remains consistent: the balance between momentum flux, resistance, and structural constraints determines the achievable efficiency envelope.
